1 Perfect Graphs

All graphs in this paper are finite, undirected and have no loops or parallel edges. We denote the chromatic number of graph G by $\chi(G)$ and the cardinality of the largest clique of G by $\omega(G)$. *Coloring* of a graph means assigning every node of a graph a color. A coloring is *valid* iff every two nodes sharing an edge have different colors. An *optimal* coloring (if exists) is a valid coloring using only $\omega(G)$ colors.

Given a graph $G = (V, E)$, sometimes by $V(G)$ and $E(G)$ we will denote a set of nodes and edges of G. Given a set $X \subseteq V$ by $G[X]$ we will denote a graph induced on X. A graph G is *perfect* iff for all $X \subseteq V(G)$ we have $\chi(G[X]) = \omega(G[X])$.

Editorial notes

- By solid lines we will mark edges, by dashed lines we will mark nonedges, when significant. Sometimes nonedges will not be marked in order not to clutter the image.

- A node is X-complete in G iff it is adjacent to all nodes in X.

- Given a path P, by P^* we will denote its inside.

Where should we put it?

Give some examples why are these interesting, some subclasses, and problems that are solvable for perfect graphs, including recognition and coloring

Given a graph G, its *complement* $\overline{G}$ is a graph with the same vertex set and in which two distinct nodes u, v are connected in $\overline{G}$ iff they are not connected in G. For example a clique in a graph becomes an independent set in its complement. A perfect graph theorem, first conjured by Berge in 1961 [Ber61] and then proven by Lovász in 1972 [Lov72] states that a graph is perfect iff its complement graph is also perfect.

A *hole* is an induced chordless cycle of length at least 4. An *antihole* is an induced subgraph whose complement is a hole. A *Berge* graph is a graph with no holes or antiholes of odd length.

In 1961 Berge conjured that a graph is perfect iff it is Berge in what has become known as a strong perfect graph conjecture. In 2001 Chudnovsky et al. have proven it and published the proof in an over 150 pages long paper "The strong perfect graph theorem" [Chu+06]. The following overview of the proof will be based on this paper and on an article withe the same name by Cornuéjols [Cor03].

Should we give some proof of that here? Maybe based on proof in [Cor03]

1.1 Strong Perfect Graph Theorem

Odd holes are not perfect, since their chromatic number is 3 and their largest cliques are of size 2. It is easy to see, that an odd antihole of size n has a chromatic number of $\frac{n+1}{2}$ and largest cliques of size $\frac{n-1}{2}$. It is therefore clear,

that if a graph is not Berge it is not perfect. To prove that every Berge graph is perfect is the proper part of the strong perfect graph theorem.

2 Recognizing Berge Graphs

2.1 Recognition algorithm Overview

2.1.1 Simple structures

Pyramids A *path* in G is an induced subgraph that is connected, with at least one node, no cycle and no node of degree larger than 2 (sometimes called chordless path). The *length* of a path or a cycle is the number of edges in it. A *triangle* in a graph is a set of three pairwise adjacent nodes.

A *pyramid* in G is an induced subgraph formed by the union of a triangle $\{b_1, b_2, b_3\}$, three paths $\{P_1, P_2, P_3\}$ and another node a, so that:

- $\forall_{1 \leq i \leq 3}\ P_i$ is a path between a and b_i

- $\forall_{1 \leq i < j \leq 3}\ a$ is the only node in both P_i and P_j and $b_i b_j$ is the only edge between $V(P_i) \setminus \{a\}$ and $V(P_j) \setminus \{a\}$.

- a is adjacent to at most one of $\{b_1, b_2, b_3\}$.

It is easy to see that every graph containing a pyramid contains an odd hole – at least two of the paths P_1, P_2, P_3 will have the same parity.
Figure 1: An example of a pyramid.

Jewels Five nodes $v_1, \ldots, v_5$ and a path P is a *jewel* iff:

- $v_1, \ldots, v_5$ are distinct nodes.

- $v_1 v_2, v_2 v_3, v_3 v_4, v_4 v_5, v_5 v_1$ are edges.

- $v_1 v_3, v_2 v_4, v_1, v_4$ are nonedges.

3

Figure 2: An example of a

- P is a path between v_1 and v_4, such that v_2, v_3, v_5 have no neighbors in its inside.

Most obvious way to find a jewel would be to enumerate all choices of $v_1, \dots v_5$, check if a choice is correct and if it is try to find a path P as required. This gives us a time of $O(|V|^7)$. We could speed it up to $O(|V|^6)$ with more careful algorithm, but since whole algorithms takes time $O(|V|^9)$ and our testing showed that time it takes to test for jewels is negligible we used this simple algorithm.

Configurations of type $\mathcal{T}_1$ A configuration of type $\mathcal{T}_1$ is a hole of length 5. To find it we simply iterate all choices of paths of length of 4, and check if there exists a fifth node to complete the hole. See paragraph 2.2.1 for more implementation details.

Configurations of type $\mathcal{T}_2$ A configuration of type $\mathcal{T}_2$ is a six $(v_1, v_2, v_3, v_4, P, X)$, such that:

- $v_1 v_2 v_3 v_4$ is a path in G.

- X is an anticomponent of the set of all $\{v_1, v_2, v_4\}$-complete nodes.

- P is a path in $G \setminus (X \cup \{v_2, v_3\})$ between v_1 and v_4 and no vertex in P^* is X-complete or adjacent to v_2 or adjacent to v_3.

Checking if configuration of type $\mathcal{T}_2$ exists in our graph is straightforward: we enumerate all paths $v_1 \dots v_4$, calculate set of all $\{v_1, v_2, v_4\}$-complete nodes and its anticomponents. Then, for each anticomponent X we check if required path P exists.

Figure 3: An example of a $\mathcal{T}_2$.

To prove that existence of $\mathcal{T}_2$ configuration implies that the graph is not berge, we will need the Roussel-Rubio lemma [RR01] as stated in [Chu+05] that says:

Lemma 2.1 (Roussel-Rubio Lemma)**.** *Let G be Berge, X be an anticonnected subset of $V(G)$, P be an odd path $p_1 \dots p_n$ in $G \setminus X$ with length at least 3, such that p_1 and p_n are X-complete and $p_2, \dots, p_{n-1}$ are not. Then:*

- *P is of length at least 5 and there exist nonadjacent $x, y \in X$, such that there are exactly two edges between x, y and P^*, namely xp_2 and yp_{n-1},*

- *or P is of length 3 and there is an odd antipath joining internal nodes of P with interior in X.*
Now, we shall prove the following:

Lemma 2.2. *If G contains configuration of type $\mathcal{T}_2$ then G is not Berge.*

Proof. Let $(v_1, v_2, v_3, v_4, P, X)$ be a configuration of type $\mathcal{T}_2$. Let us assume that G is not Berge and consider the following:

- If P is even, then $v_1, v_2, v_3, v_4, P, v_1$ is an odd hole,

- If P is of length 3. Let us name its nodes v_1, p_2, p_3, v_4. It follows from Lemma 2.1, that there exists an odd antipath between p_2 and p_3 with interior in X. We can complete it with $v_2 p_2$ and $v_2 p_3$ into an odd antihole.

- If P is odd with the length of at least 5 , it follows from Lemma 2.1 that we have $x, y \in X$ with only two edges to P being $x p_2$ and $y p_{n-1}$. This gives us an odd hole: $v_2, x, p_2, \ldots, p_{n-1}, y, v_2$.

$\square$

> I merged a couple of proofs from [Chu+06], check in the morning if this is correct.

> check in the morning

Finding and Using Half-Cleaners.

Overview of proof of why algorithm using Half-Cleaners is correct.

2.2 Implementation

Anything interesting about algo/data structure?

2.2.1 Optimizations

Bottlenecks in performance (next path, are vectors distinct etc).

> In our graph preprocessing we have a pointer to next edge in order to speed up generating next path.

> We used callgrind to get idea of methods crucial for time.

> In general enumerating all paths is crucial. As is checking if vector has distinct values.

> Jewels – we iterate all possibly chordal paths and check if they are ok - much faster

> $\mathcal{T}_1$ – we iterate all paths of length 4 and check if there exists a fifth node to complete the hole - much faster than iterating nodes.

Validity tests - unit tests, tests of bigger parts, testing vs known answer and vs naive.

2.3 Parallelism with CUDA (?)

TODO

2.4   Experiments

Naive algorithm - brief description, bottlenecks optimizations (makes huge difference).

Description of tests used.

Results and Corollary - almost usable algorithm.

3   Coloring Berge Graphs

3.1   Ellipsoid method

Description.

Implementation.

Experiments and results.

3.2   Combinatorial Method

Cite the paper.

On its complexity - point to appendix for pseudo-code.

Appendices

A   Perfect Graph Coloring algorithm
